This invention relates to a bicycle derailleur having a diagonally movable operating plate which is coupled to a cycle fork so as to have free lateral movement, and which plate is rockable in opposite directions between the limit stops. In the past, various frame derailleurs have been proposed which cooperate with the rear wheel sprocket so as to select one of a plurality of front sprockets. In conventional derailleur mechanisms, two straight linkage arms are pivotally coupled to a fixed end of a frame crank and of the bicycle frame, and to a pivotable front derailleur of the bicycle, and to a rear derailleur mounted on the bicycle frame. The free end of each linkage arm is coupled to a pivotable operating plate. A first one of the linkage arms is typically utilized for shifting the rear derailleur, and a second linkage arm is coupled to the operating plate for shifting the front derailleur. Both linkage arms are pivoted in unison at their respective pivotable end on the bicycle frame. The operating plate is also coupled to the bicycle frame and to the other one of the linkage arms in a manner which permits the operating plate to be rocked or pivoted between the limit stops. As shown in U.S. Pat. No. 4,300,777 issued to Harrison, the operating plate is mounted on one side of the bicycle crank, and an actuating rod connected to the operating plate extends through an opening in the frame crank. A spring biases the operating plate toward the limit stops
